

Observations of task 2.

In the output plot, there are x points and red circle points, the x points are outliers and the RANSAC algorithm has managed to identify those points as outliers and then draw a line through the red circle points which is the “real” data with actually predictable behavior and the line has managed to predict just that.

The RANSAC algorithm managed to distinguish the 2 data types from each other by calculating their distances to the line that it predicts to be the line of best fit and from that if the distance is greater or smaller than the threshold “ t ” then they will be classified as outliers or inliers.
